

Part of Bank charted in fig. 46 photographed three years before Chart 46A was made; it shows the earliest phase of colonization by *Salicornia radicans*, which in places has already orientated itself transversely to the current

Well-developed hummocks in phase 1 (cf. fig. 46A) with their belts of *S. radicans*. The white wisps consist of bleached *Zostera* leaves entangled from the drift

HUMMOCK DEVELOPMENT (BOUCHE D'ERQUY, BRITTANY)
